Chapter 13

Disk Storage, Basic File Structures, and Hashing

Chapter Outline

- Disk Storage Devices
- Files of Records
- Operations on Files
- Unordered Files
- Ordered Files
- Hashed Files
 - Dynamic and Extendible Hashing Techniques
- RAID Technology

Disk Storage Devices

- Preferred secondary storage device for high storage capacity and low cost.
- Data stored as magnetized areas on magnetic disk surfaces.
- A disk pack contains several magnetic disks connected to a rotating spindle.
- Disks are divided into concentric circular tracks on each disk surface.
 - Track capacities vary typically from 4 to 50 Kbytes or more

- A track is divided into smaller blocks or sectors
 - because it usually contains a large amount of information
- The division of a track into sectors is hard-coded on the disk surface and cannot be changed.
 - One type of sector organization calls a portion of a track that subtends a fixed angle at the center as a sector.
- A track is divided into blocks.
 - The block size B is fixed for each system.
 - Typical block sizes range from B=512 bytes to B=4096 bytes.
 - Whole blocks are transferred between disk and main memory for processing.

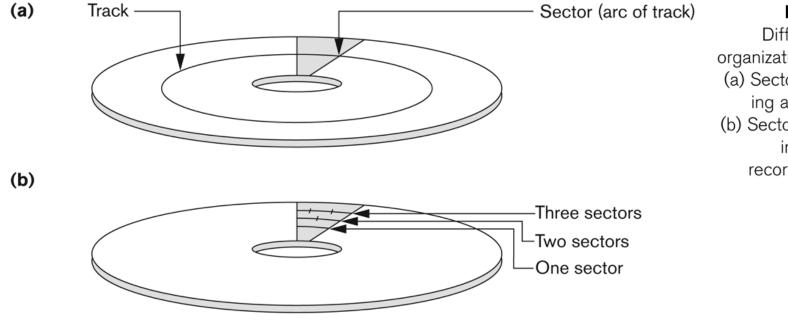

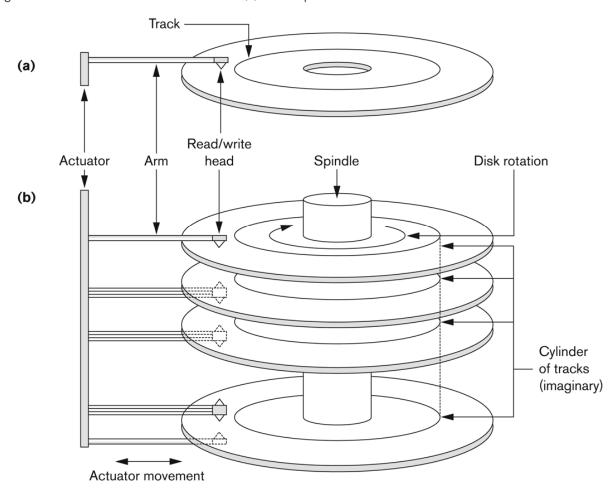

Figure 13.2

Different sector organizations on disk.

- (a) Sectors subtending a fixed angle.
- (b) Sectors maintaining a uniform recording density.

- A read-write head moves to the track that contains the block to be transferred.
 - Disk rotation moves the block under the read-write head for reading or writing.
- A physical disk block (hardware) address consists of:
 - a cylinder number (imaginary collection of tracks of same radius from all recorded surfaces)
 - the track number or surface number (within the cylinder)
 - and block number (within track).
- Reading or writing a disk block is time consuming because of the seek time s and rotational delay (latency) rd.
- Double buffering can be used to speed up the transfer of contiguous disk blocks.

Figure 13.1
(a) A single-sided disk with read/write hardware. (b) A disk pack with read/write hardware.

Typical Disk Parameters

Table 13.1 Specifications of Typical High-end Cheetah Disks from Seagate

Description	Cheetah 10K.6	Cheetah 10K.7
Model Number	ST3146807LC	ST3300007LW
Form Factor (width)	3.5 inch	3.5 inch
Form Factor (height)	1 inch	1 inch
Height	25.4 mm	25.4 mm
Width	101.6 mm	101.6 mm
Length	146.05 mm	146.05 mm
Weight	0.73 Kg	0.726 kg
Capacity/Interface		
Formatted Capacity	146.8 Gbytes	300 Gbytes
Interface Type	80-pin	68-pin
Configuration		
Number of disks (physical)	4	4
Number of heads (physical)	8	8
Number of Cylinders	49,854	90,774
Total Tracks		726,192
Bytes per Sector	512	512
Areal Density	36,000 Mb/sq.inch	
Track Density	64,000 Tracks/inch	105,000 Tracks/inch
Recording Density	570,000 bits/inch	658,000 bits/inch
Bytes/Track (avg)		556
Performance		
Transfer Rates		
Internal Transfer Rate (min)	475 Mb/sec	472 Mb/sec
Internal Transfer Rate (max)	840 Mb/sec	944 Mb/sec
Formated Int. Transfer Rate (min)	43 MB/sec	59 MB/sec
Formated Int. Transfer Rate (max)	78 MB/sec	118 MB/sec
External I/O Transfer Rate (max)	320 MB/sec	320 MB/sec
Average Formatted Transfer Rate	59.9 MB/sec	59.5 MB/sec
Seek Times		
Avg. Seek Time (Read)	4.7 ms (typical)	4.7 ms (typical)
Avg. Seek Time (Write)	5.2 ms (typical)	5.3 ms (typical)
Track-to-track, Seek, Read	0.3 ms (typical)	0.2 ms (typical)
Track-to-track, Seek, Write	0.5 ms (typical)	0.5 ms (typical)
Full Disc Seek, Read		9.5 ms (typical)
Full Disc Seek, Write		10.3 ms (typical)
Average Latency	2.99 ms	3 msec
Other		
Default Buffer (cache) size	8,000 KB	8,192 KB
Spindle Speed	10000 RPM	10000 RPM
Power-on to Ready Time		25 sec
,

Records/Tuples

- Fixed and variable length records
- Records contain fields which have values of a particular type
 - E.g., amount, date, time, age
- Fields themselves may be fixed length or variable length
- Variable length fields can be mixed into one record:
 - Separator characters or length fields are needed so that the record can be "parsed."

Blocking

Blocking:

- Refers to storing a number of records in one block on the disk.
- Blocking factor (bfr) refers to the number of records per block.
- There may be empty space in a block if an integral number of records do not fit in one block.
- Spanned Records:
 - Refers to records that exceed the size of one or more blocks and hence span a number of blocks.

Files of Records

- A file is a sequence of records, where each record is a collection of data values (or data items).
- A file descriptor (or file header) includes information that describes the file, such as the field names and their data types, and the addresses of the file blocks on disk.
- Records are stored on disk blocks.
- The blocking factor bfr for a file is the (average) number of file records stored in a disk block.
- A file can have fixed-length records or variable-length records.

Files of Records (contd.)

- File records can be unspanned or spanned
 - Unspanned: no record can span two blocks
 - Spanned: a record can be stored in more than one block
- The physical disk blocks that are allocated to hold the records of a file can be contiguous, linked, or indexed.
- In a file of fixed-length records, all records have the same format.
 - Usually, unspanned blocking is used with such files.
- Files of variable-length records require additional information to be stored in each record, such as separator characters and field types.
 - Usually spanned blocking is used with such files.

- B (block size)=1024 bytes
- R (record size) = 256 bytes
- r (file size in terms of number of records) = 5000
- bfr = floor(1024/256) = 4
- b (file size in terms of no. of blocks needed) =
 ceiling(r/bfr) = ceiling (5000/4) = 1250

Operation on Files

- Typical file operations include:
 - OPEN: Readies the file for access, and associates a pointer that will refer to a current file record at each point in time.
 - FIND: Searches for the first file record that satisfies a certain condition, and makes it the current file record.
 - **FINDNEXT**: Searches for the next file record (from the current record) that satisfies a certain condition, and makes it the current file record.
 - READ: Reads the current file record into a program variable.
 - INSERT: Inserts a new record into the file & makes it the current file record.
 - DELETE: Removes the current file record from the file, usually by marking the record to indicate that it is no longer valid.
 - MODIFY: Changes the values of some fields of the current file record.
 - CLOSE: Terminates access to the file.
 - **REORGANIZE**: Reorganizes the file records.
 - For example, the records marked deleted are physically removed from the file or a new organization of the file records is created.
 - READ_ORDERED: Read the file blocks in order of a specific field of the file.

Unordered Files

- Also called a heap or a pile file.
- New records are inserted at the end of the file.
- A linear search through the file records is necessary to search for a record.
 - This requires reading and searching half the file blocks on the average, and is hence quite expensive.
- Record insertion is quite efficient.
- Reading the records in order of a particular field requires sorting the file records.

Ordered Files

- Also called a sequential file.
- File records are kept sorted by the values of an ordering field.
- Insertion is expensive: records must be inserted in the correct order.
 - It is common to keep a separate unordered overflow (or transaction) file for new records to improve insertion efficiency; this is periodically merged with the main ordered file.
- A binary search can be used to search for a record on its ordering field value.
 - This requires reading and searching log₂ of the file blocks on the average, an improvement over linear search.
- Reading the records in order of the ordering field is quite efficient.

Average Access Times

 The following table shows the average access time to access a specific record for a given type of file

TABLE 13.2 AVERAGE ACCESS TIMES FOR BASIC FILE ORGANIZATIONS

Type of Organization	ACCESS/SEARCH METHOD	AVERAGE TIME TO ACCESS A SPECIFIC RECORD
Heap (Unordered)	Sequential scan (Linear Search)	b/2
Ordered Ordered	Sequential scan Binary Search	$b/2$ $\log_2 b$

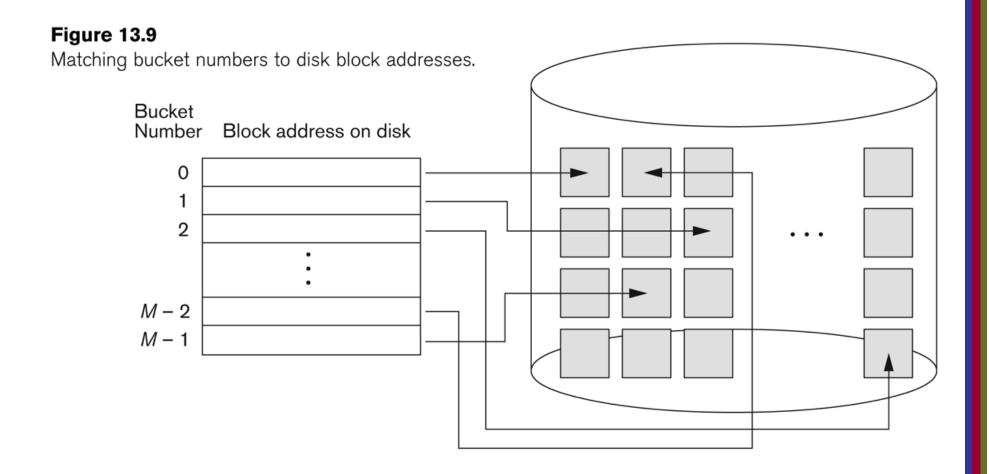

Hashed Files

- Hashing for disk files is called External Hashing
- The file blocks are divided into M equal-sized buckets, numbered bucket₀, bucket₁, ..., bucket_{M-1}.
 - Typically, a bucket corresponds to one (or a fixed number of) disk block.
- One of the file fields is designated to be the hash key of the file.
- The record with hash key value K is stored in bucket i, where i=h(K), and h is the hashing function.
- Search is very efficient on the hash key.
- Collisions occur when a new record hashes to a bucket that is already full.
 - An overflow file is kept for storing such records.
 - Overflow records that hash to each bucket can be linked together.

Hashed Files (contd.)

- There are numerous methods for collision resolution, including the following:
 - Open addressing: Proceeding from the occupied position specified by the hash address, the program checks the subsequent positions in order until an unused (empty) position is found.
 - Chaining: For this method, various overflow locations are kept, usually by extending the array with a number of overflow positions. In addition, a pointer field is added to each record location. A collision is resolved by placing the new record in an unused overflow location and setting the pointer of the occupied hash address location to the address of that overflow location.
 - Multiple hashing: The program applies a second hash function if the first results in a collision. If another collision results, the program uses open addressing or applies a third hash function and then uses open addressing if necessary.

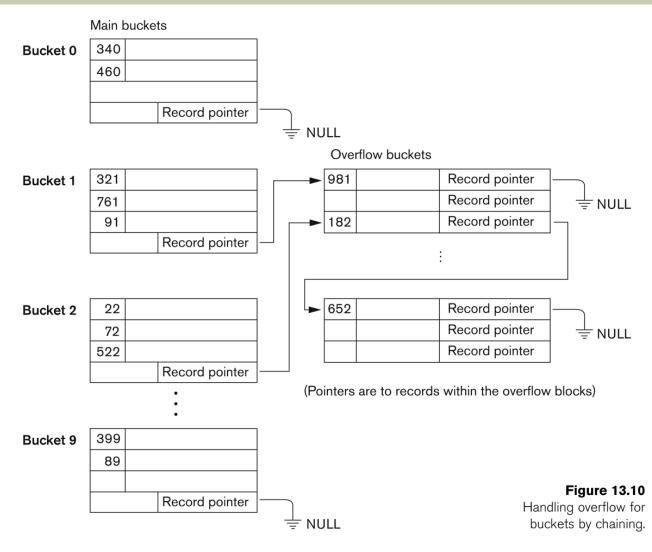

Hashed Files (contd.)

Hashed Files (contd.)

- To reduce overflow records, a hash file is typically kept 70-80% full.
- The hash function h should distribute the records uniformly among the buckets
 - Otherwise, search time will be increased because many overflow records will exist.
- Main disadvantages of static external hashing:
 - Fixed number of buckets M is a problem if the number of records in the file grows or shrinks.
 - Ordered access on the hash key is quite inefficient (requires sorting the records).

Hashed Files - Overflow handling

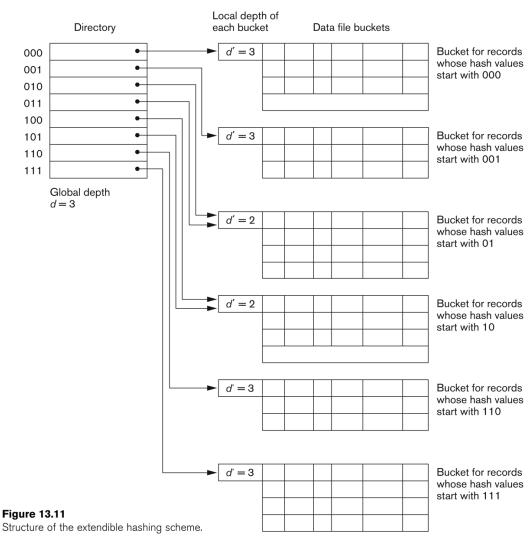

Dynamic And Extendible Hashed Files

- Dynamic and Extendible Hashing Techniques
 - Hashing techniques are adapted to allow the dynamic growth and shrinking of the number of file records.
 - These techniques include the following: dynamic hashing, extendible hashing, and linear hashing.
- Both dynamic and extendible hashing use the binary representation of the hash value h(K) in order to access a directory.
 - In dynamic hashing the directory is a binary tree.
 - In extendible hashing the directory is an array of size 2^d where d is called the global depth.

Dynamic And Extendible Hashing (contd.)

- The directories can be stored on disk, and they expand or shrink dynamically.
 - Directory entries point to the disk blocks that contain the stored records.
- An insertion in a disk block that is full causes the block to split into two blocks and the records are redistributed among the two blocks.
 - The directory is updated appropriately.
- Dynamic and extendible hashing do not require an overflow area.
- Linear hashing does require an overflow area but does not use a directory.
 - Blocks are split in *linear order* as the file expands.

Extendible Hashing

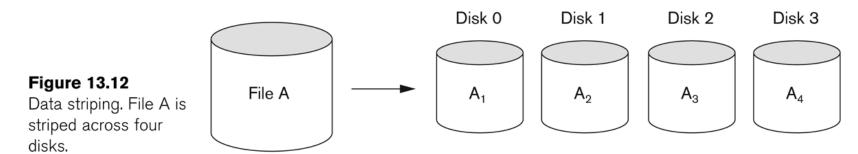

Parallelizing Disk Access using RAID Technology.

- Secondary storage technology must take steps to keep up in performance and reliability with processor technology.
- A major advance in secondary storage technology is represented by the development of RAID, which originally stood for Redundant Arrays of Inexpensive Disks.
- The main goal of RAID is to even out the widely different rates of performance improvement of disks against those in memory and microprocessors.

RAID Technology (contd.)

- A natural solution is a large array of small independent disks acting as a single higherperformance logical disk.
- A concept called data striping is used, which utilizes parallelism to improve disk performance.
- Data striping distributes data transparently over multiple disks to make them appear as a single large, fast disk.

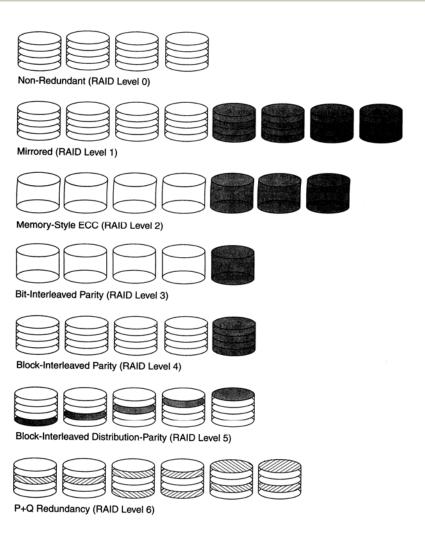

RAID Technology (contd.)

- Different raid organizations were defined based on different combinations of the two factors of granularity of data interleaving (striping) and pattern used to compute redundant information.
 - Raid level 0 has no redundant data and hence has the best write performance at the risk of data loss
 - Raid level 1 uses mirrored disks.
 - Raid level 2 uses memory-style redundancy by using Hamming codes, which contain parity bits for distinct overlapping subsets of components. Level 2 includes both error detection and correction.
 - Raid level 3 uses a single parity disk relying on the disk controller to figure out which disk has failed.
 - Raid Levels 4 and 5 use block-level data striping, with level 5 distributing data and parity information across all disks.
 - Raid level 6 applies the so-called P + Q redundancy scheme using Reed-Soloman codes to protect against up to two disk failures by using just two redundant disks.

Use of RAID Technology (contd.)

- Different raid organizations are being used under different situations
 - Raid level 1 (mirrored disks) is the easiest for rebuild of a disk from other disks
 - It is used for critical applications like logs
 - Raid level 2 uses memory-style redundancy by using Hamming codes, which contain parity bits for distinct overlapping subsets of components.
 - Level 2 includes both error detection and correction.
 - Raid level 3 (single parity disks relying on the disk controller to figure out which disk has failed) and level 5 (block-level data striping) are preferred for Large volume storage, with level 3 giving higher transfer rates.
- Most popular uses of the RAID technology currently are:
 - Level 0 (with striping), Level 1 (with mirroring) and Level 5 with an extra drive for parity.
- Design Decisions for RAID include:
 - Level of RAID, number of disks, choice of parity schemes, and grouping of disks for block-level striping.

Use of RAID Technology (contd.)

Trends in Disk Technology

TABLE 13.3 TRENDS IN DISK TECHNOLOGY

	1993 Parameter Values*	HISTORICAL RATE OF IMPROVEMENT PER YEAR (%)*	CURRENT (2003) VALUES**
Areal density	50-150 Mbits/sq. inch	27	36 Gbits/sq. inch
Linear density	40,000–60,000 bits/inch	13	570 Kbits/inch
Inter-track density	1500-3000 tracks/inch	10	64,000 tracks/inch
Capacity (3.5" form factor)	100–2000 MB	27	146 GB
Transfer rate	3–4 MB/s	22	43-78 MB/sec
Seek time	7–20 ms	8	3.5–6 msec

Storage Area Networks

- The demand for higher storage has risen considerably in recent times.
- Organizations have a need to move from a static fixed data center oriented operation to a more flexible and dynamic infrastructure for information processing.
- Thus they are moving to a concept of Storage Area Networks (SANs).
 - In a SAN, online storage peripherals are configured as nodes on a high-speed network and can be attached and detached from servers in a very flexible manner.
- This allows storage systems to be placed at longer distances from the servers and provide different performance and connectivity options.

Storage Area Networks (contd.)

- Advantages of SANs are:
 - Flexible many-to-many connectivity among servers and storage devices using fiber channel hubs and switches.
 - Up to 10km separation between a server and a storage system using appropriate fiber optic cables.
 - Better isolation capabilities allowing non-disruptive addition of new peripherals and servers.
- SANs face the problem of combining storage options from multiple vendors and dealing with evolving standards of storage management software and hardware.
